Therefore, the operations of the microprocessors used in the machines are not discussed they are explained in terms of from sensors to the input of the DC controller PCB and from the output of the DC controller PCB to the loads. For this reason, laser radiation emitted inside this machine is hermetically sealed within the protective housing and external cover. No radiation can leak from the machine in the normal operation of the product by the user. These regulations apply to all laser products produced on and after August 1, 1976, and a laser product cannot be sold unless it has been certified to comply with the regulations. The following is the label used to indicate that the product has been certified under the regulations, and all laser products sold in the US must bear the label. If exposed to laser light, the human eye can irreparably be damaged. Never attempt to disassemble the laser scanner unit. It is not designed for servicing in the field. It may explode. They are likely to react with each other. It, however, does not identify a BD error under the following condition The resulting toner image is then transferred to paper by the work of the transfer charging roller, and the paper is sent to the fixing assembly.

The surface of the photosensitive drum is cleaned by the cleaning blade so that it is free of residual toner; after cleaning, the primary charging roller once again charges the surface to an even, negative potential to prepare for the formation of a new static, latent image. To protect the drum against light, the machine is equipped with a drum cover shutter. The drum cover shutter must never be opened unless doing so proves to be absolutely necessary. The paper is then moved from the transfer assembly to the fixing assembly by the feed roller; it is ultimately delivered outside the machine by the work of the delivery roller. If the faceup cover is closed, on the other hand, the paper is moved along the feed guide of the cover, and is delivered facedown at the top of the machine by the work of the facedown delivery roller. The machine identifies a pickup delay jam if the top sensor does not detect the leading edge of paper within 1.2 sec after the 2nd pickup operation. The machine is designed to identify such a jam so as to prevent wrapping paper from fully moving into the fixing assembly. If the temperature of the fixing heater abnormally increases and the voltage of the fixing heater temperature detection signal from the sub thermistor reaches about 2.779 V equivalent of 320 deg C or more, the CPU causes the fixing heater drive signal to go Low and turns off the photo triac couple, thus cutting off the power to the fixing heater. Therefore, the operations of the microprocessors used in the machines are not discussed they are explained in terms of from sensors to the input of the DC controller PCB and from the output of the DC controller PCB to the loads. The CPU of the reader unit interprets input signals and the signals from the host machine, and generates signals used to drive such DC loads as motors and solenoids. The ADF controller PCB does not have a memory area, and the EEPROM of the reader controller PCB is used to store such data as service mode settings. It uses 2 motors for picking up and moving originals. As a result, the last original sensor PI8 generates the last original detection signal ENDS; when the last original moves past the original sensor PI9, the sensor generates the

original absent signal EMPS to communicate to the host machine that the original being picked up is the last original. When the Start key is pressed, the original size is checked and communicated to the host machine in real time. The original width detection volume operates in conjunction with the slide guide, and the movement of the guide changes the resistance of the volume analog. The ADF controller checks the changes in the resistance through the original size signal VR to identify the length of the original in cross feed. Some paper sizes, however, are located appreciably near each other, possibly stopping the guide at the wrong position. The machine uses the length of feed with reference to the number of clock pulses from the feed motor M1 generated from when the read sensor PI3 goes on until when the sensor goes off.

The read sensor I3 generates the last original detection signal ENDS for the ADF controller PCB. The stopper moves up in keeping with the movement of the pickup roller unit. The separation plate and the separation pad serve to prevent multiple feeding. In stream reading mode, the machine moves the original over the glass of the host machine for scanning. The host machine's scanner is held in position. The stopper moves up in keeping with the movement of the pickup unit; the separation pad and the separation plate are used to prevent multiple feeding that otherwise may occur at time of pickup. All this while, the separation roller drive shaft driven by way of the spring oneway clutch remains at rest at the upper limit of the pickup roller; the separation roller rotates by the friction against paper and by the work of the oneway clutch. As soon as reading ends, image leading edge signal going off, the locking solenoid SL1 goes on so that the delivery reversing roller gets locked in place, causing the paper to move to the delivery assembly.
